

Incident Lifecycle Automation in ServiceNow

Phase 9: Child Incident Creation

Purpose: This phase demonstrates how a child incident can be created from an existing parent incident. It helps separate and track a related issue while maintaining a clear relationship with the original incident.

Steps and Additional Points

- Open the parent incident and go to the **Related Records** tab.
- Select **Child Incidents** and click **New** to create a related incident.
- Enter the Short Description as **Unable to connect to Corporate VPN**.
- Select an appropriate caller/user for the child incident.
- Enter the description: **User receiving VPN authentication failure error**.
- Save the record and make a note of the newly generated incident number.
- Return to the parent incident and open **Related Records** again.
- Verify that the newly created child incident is displayed in the Child Incidents list.
- The child incident allows a related issue to be assigned, investigated, and tracked separately without losing its connection to the parent incident.
- Parent-child relationships improve incident organization, visibility, accountability, and reporting when multiple issues are associated with a common problem.
- The linked records preserve the incident history and help support teams understand the relationship between the original issue and related incidents.

Outcome

A child incident is successfully created and linked to the parent incident. The child record can now be managed independently while remaining associated with the original VPN-related incident. This provides better tracking, organization, and visibility throughout the incident lifecycle.
